## **Design of Smart Neonatal Health Monitoring System using Sensor Mobile Cloud Computing**

Computerized wellbeing checking and ready framework improvement is a requesting research zone today. A large portion of the presently accessible checking and controlling restorative gadgets are wired which limits freeness of workplace. Remote sensor arranges (WSN) is a superior option in such a situation. The neonatal emergency unit used to deal with wiped out and untimely neonates. Hypothermia is an autonomous hazard factor for neonatal mortality and horribleness. To avert it a robotized checking framework is required. In this Letter, a computerized neonatal wellbeing checking framework is outlined utilizing sensor portable distributed computing (SMCC). SMCC depends on WSN and MCC. In the creators' framework temperature sensor, quickening sensor and heart rate estimation sensor are utilized to screen body temperature, speeding up because of body development and heart rate of neonates. The sensor information is put away in the cloud. The wellbeing individual persistently screens and gets to this information through the cell phone utilizing an Android Application for neonatal checking. At the point when a strange circumstance emerges, a caution is created in the cell phone of the wellbeing individual. With alarming wellbeing proficient utilizing such a robotized framework, early care is given to the influenced babies and the likelihood of recuperation is expanded.
